An Introduction to Python

Parham Alvani Amirkabir University of Technology

parham.alvani@gmail.com May 15, 2015

Keyboard Input

► The input() function reads a line from sys.stdin and returns it with the trailing newline stripped.

```
name = input("Enter your input: ")
print("Received input is : ", name)
```

File IO

- ► The open Function
- ► The file Object
- ► The close() Method
- ► The write() Method
- ► The read() Method

The open Function

- ▶ Before you can read or write a file, you have to open it using Python's built-in open() function.
- ▶ This function creates a file object, which would be utilized to call other support methods associated with it.

```
file object = open(file_name [, access_mode][, buffering])
```

```
fo = open("foo.txt", "w")
```

The write() Method

► The write() method writes any string to an open file.

```
# Open a file
fo = open("foo.txt", "wb")
fo.write( "Python is a great language.\nYeah its great!!\n")
# Close opend file
fo.close()
```

 Parham Alvani (AUT)
 Introduction

 5 / 31

The read() Method

fileObject.read([count])

► The read() method reads a string from an open file.

```
# Open a file
fo = open("foo.txt", "r+")
str = fo.read(10);
print "Read String is : ", str
# Close opend file
fo.close()
```

Parham Alvani (AUT) Introduction May 15, 2015

The readline() Method

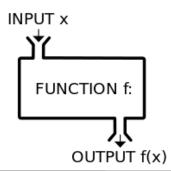

- ▶ Read one entire line from the file.
- ▶ A trailing newline character is kept in the string.
- ► If the size argument is present and non-negative, it is a maximum byte count (including the trailing newline) and an incomplete line may be returned.

fileObject.readline([size])

Parham Alvani (AUT) Introduction May 15, 2015 7 / 31

Functions

- Function blocks begin with the keyword def, followed by the function name and parentheses.
- ► Any input parameters or arguments should be placed within these parentheses.
- ► The first statement of a function can be an optional statement the documentation string of the function or docstring.

Functions

```
def square(x):
    return x * x

def hello():
    return "Hello"

def printme( statement ):
    "This prints a passed string into this function"
    print statement
    return
```

Lambda

- ▶ Python supports simple anonymous functions through the lambda form.
- ► The executable body of the lambda must be an expression and can't be a statement, which is a restriction that limits its utility.

foo = lambda x: x * x

Parham Alvani (AUT) Introduction May 15, 2015

Classes

- ▶ The class statement creates a new class definition.
- ► The name of the class immediately follows the keyword class followed by a colon as follows

Classes

```
class Employee:
    11 11 11
    Common base class for all employees
    11 11 11
    empCount = 0
    def __init__(self, name, salary):
        self.name = name
        self.salary = salary
        Employee.empCount += 1
    def displayCount(self):
        print "Total Employee %d" % Employee.empCount
    def displayEmployee(self):
        print "Name : ", self.name, ", Salary: ", self.salary
emp1 = Employee("Zara", 2000)
```

Garbage Collection

▶ Python deletes unneeded objects automatically to free the memory space.

Parham Alvani (AUT) Introduction May 15, 2015 13 / 31

Inheritance

▶ Instead of starting from scratch, you can create a class by deriving it from a preexisting class by listing the parent class in parentheses after the new class name.

 Parham Alvani (AUT)
 Introduction
 May 15, 2015
 14 / 31

Inheritance

```
class SubClassName (ParentClass1[, ParentClass2, ...]):
    """
    Optional class documentation string
    """
    # class_suite
```

- ► __init__(self [,args...]) : Constructor (with any optional arguments)
- ► __del__(self) : Destructor, deletes an object
- __repr__(self) : Evaluatable string representation
- ► __str__(self) : Printable string representation
- ► __lt__(self, other):
- ► __le__(self, other):
- ► __eq__(self, other):
- ► __ne__(self, other):
- ► __gt__(self, other):
- ► __ge__(self, other):

These are the so-called rich comparison methods, and are called for comparison operators in preference to __cmp__() below.

Base Overloading Methods

- ► __cmp__ (self, x) : Called by comparison operations if rich comparison is not defined.
- ► __add__(self, other):
- __sub__(self, other):
- __mul__(self, other):
- ► __floordiv__(self, other):
- ► __mod__(self, other):
- __divmod__(self, other):
- __pow__(self, other[, modulo]):

Parham Alvani (AUT) Introduction May 15, 2015 17 / 31

```
► __lshift__( self, other ):
```

- __rshift__(self, other):
- ► __and__(self, other):
- __xor__(self, other):
- ► __or__(self, other):

These methods are called to implement the binary arithmetic operations

```
+, -, *, //, \%, \, \mathsf{divmod}(), \, \mathsf{pow}(), \, **, <<, >>, \, \&, \, \hat{\ }, \, |
```

Data Hiding

- ► An object's attributes may or may not be visible outside the class definition.
- ► You need to name attributes with a double underscore prefix, and those attributes then are not be directly visible to outsiders.
- ► Python protects those members by internally changing the name to include the class name.
- ► You can access such attributes as object._className__attrName

Parham Alvani (AUT) Introduction May 15, 2015 19 / 31

```
#!/usr/bin/python
class JustCounter:
    __secretCount = 0
    def count(self):
        self. secretCount += 1
        print self.__secretCount
counter = JustCounter()
counter.count()
counter.count()
print counter.__secretCount
```

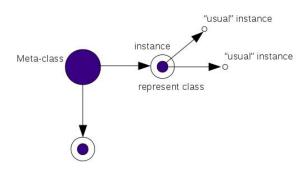

Data Hiding

```
Traceback (most recent call last):
File "test.py", line 12, in <module>
print counter.__secretCount
AttributeError: JustCounter instance has no attribute '__secretCount'
```

What is a metaclass in Python?

- A metaclass is the class of a class
- ► Like a class defines how an instance of the class behaves, a metaclass defines how a class behaves.
- ▶ A class is an instance of a metaclass.

Multiple Inheritance

- ► Method Resolution Order (MRO)
- ► C3 Algorithm

C3 linearization

► The C3 superclass linearization is an algorithm used primarily to obtain the order in which methods should be inherited (the "linearization") in the presence of multiple inheritance, and is often termed "MRO" for Method Resolution Order.

```
class O
class A extends O
class B extends O
class C extends O
class D extends O
class E extends O
class K1 extends A, B, C
class K2 extends D, B, E
class K3 extends D, A
class Z extends K1, K2, K3
```

```
L(0) := [0]
L(A) := [A] + merge(L(0), [0])
= [A] + merge([0], [0])
= [A, 0]
L(B) := [B, 0]
L(C) := [C, 0]
L(D) := [D, 0]
L(E) := [E, 0]
L(K1) := [K1] + merge(L(A), L(B), L(C), [A, B, C])
= [K1] + merge([A, O], [B, O], [C, O], [A, B, C])
= [K1, A] + merge([0], [B, 0], [C, 0], [B, C])
= [K1, A, B] + merge([0], [0], [C, 0], [C])
= [K1, A, B, C] + merge([0], [0], [0])
= [K1, A, B, C, 0]
```

```
L(K2) := [K2] + merge(L(D), L(B), L(E), [D, B, E])
= [K2] + merge([D, 0], [B, 0], [E, 0], [D, B, E])
= [K2, D] + merge([0], [B, 0], [E, 0], [B, E])
= [K2, D, B] + merge([0], [0], [E, 0], [E])
= [K2, D, B, E] + merge([0], [0], [0])
= [K2, D, B, E, 0]
L(K3) := [K3] + merge(L(D), L(A), [D, A])
= [K3] + merge([D, 0], [A, 0], [D, A])
= [K3, D] + merge([0], [A, 0], [A])
= [K3, D, A] + merge([0], [0])
= [K3, D, A, O]
```

```
L(Z) := [Z] + merge(L(K1), L(K2), L(K3), [K1, K2, K3])

= [Z] + merge([K1, A, B, C, O], [K2, D, B, E, O], [K3, D, A, O], [K1, K2, K3])

= [Z, K1] + merge([A, B, C, O], [K2, D, B, E, O], [K3, D, A, O], [K2, K3])

= [Z, K1, K2] + merge([A, B, C, O], [D, B, E, O], [K3, D, A, O], [K3])

= [Z, K1, K2, K3] + merge([A, B, C, O], [D, B, E, O], [D, A, O])

= [Z, K1, K2, K3, D] + merge([A, B, C, O], [B, E, O], [A, O])

= [Z, K1, K2, K3, D, A] + merge([B, C, O], [B, E, O], [O])

= [Z, K1, K2, K3, D, A, B] + merge([C, O], [E, O], [O])

= [Z, K1, K2, K3, D, A, B, C, E] + merge([O], [O], [O])

= [Z, K1, K2, K3, D, A, B, C, E] + merge([O], [O], [O])

= [Z, K1, K2, K3, D, A, B, C, E, O]
```

Class method differences in Python

- Bound, unbound and static
- ▶ Basically, a call to a member function a bound function is translated to a call to an unbound method.

```
class Test(object):
    def method_one(self):
        print "Called method_one"

a_test = Test()

a_test.method_one()
# is translated to
Test.method one(a test)
```

Parham Alvani (AUT) Introduction May 15, 2015

Class method differences in Python

► The @staticmethod tells the built-in default metaclass type (the class of a class) to not create bound methods for method_two.

```
class Test(object):
    @staticmethod
    def method_two():
        print "Called method two"

a_test = Test()
a_test.method_two()
# is translated to
Test.method_two()
```
